Lab 1 - Quick solution:

The intent of this program is to demonstrate a simple Automatic event driven PLC program based on the Assembler Video provided for FactoryIO.

Advance_X_Dwell is needed to account for the delay between issuing a command and getting feedback. Since there is no Advanced Sensor and Move_X must stay on to keep the X-Axis in the Advanced Position, the Dwell and NOT Moving_X can be used in place of Advanced instead of creating a specific Bit.

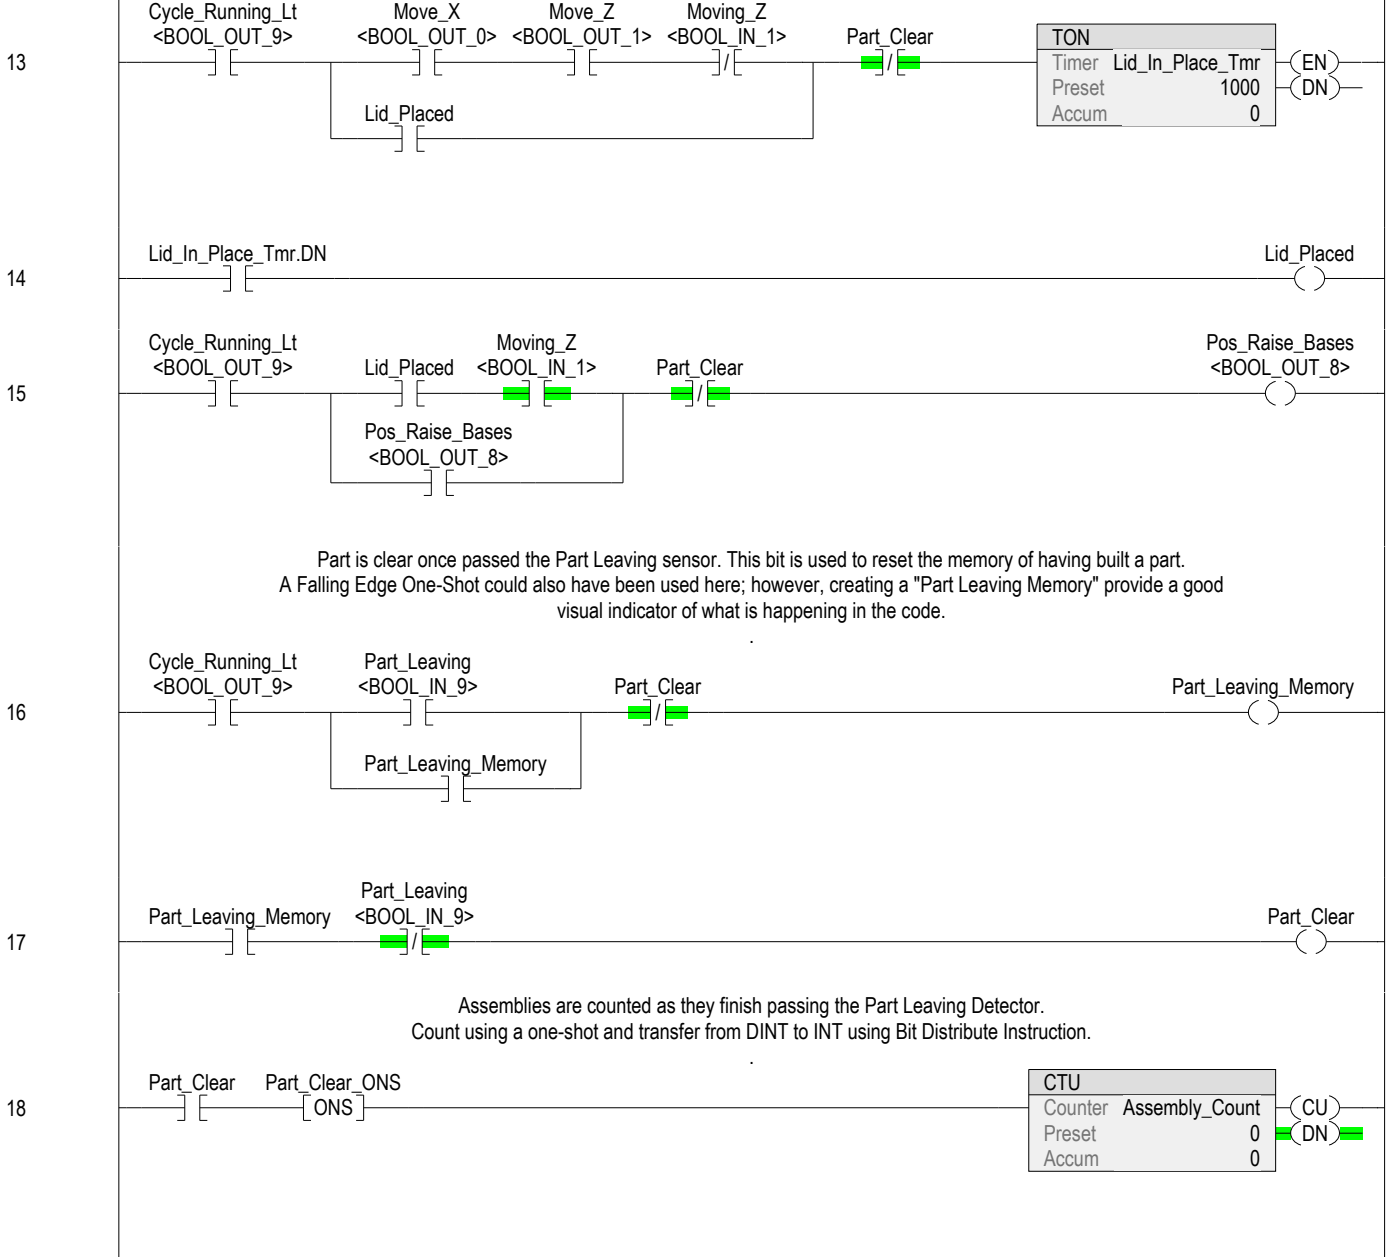

There is no limit switch for the Z-Axis and we need to ensure the Z-Axis is fully raised before Advancing X.

Using the Move Command and Moving Feedback, Z_Raising_Memory is Sealed in. When the Axis stopped moving, Raised is turned ON and Sealed in at the same time, releasing the seal on the Raising Memory Bit. Note that the technique used for the Axis Motion above could have worked as well. This just demonstrate an alternate method (there is no "correct" method, however, unique bits would be more structured - See LAB 2) The Axis responds same as controls using a Single-Ended-Spring-Return Solenoid. Turning OFF Move_Z Raises the Cylinder.

This is a variation of how to detect the end of a motion using the Move Command the Moving Feedback.
 Instead of creating a memory that Z is Advancing, Move_Z ON and Moving_Z OFF are conditions to detect end of stroke. However, since the Moving Status of the Axis does not respond immediately to the Move Command, there is a short period of time at the beginning the stroke where the Move Command is ON and the Axis Moving Input has not turned on.
 Although not technically a RACE condition, a timer can be utilized to ignore the overlap. On a real machine, the Returned Limit Switch would still be ON, for example, during a short period of time after Solenoid Turns on and the cylinder actually starts to move. Good "Real World" discussion.
